Background

Acute myeloid leukaemia (AML) is the second most common type of leukaemia in children. On the genome level it is characterised by complex translocations and short variants that are often difficult to resolve using standard reference-based methods.

In contrast, a **personal pangenome** approach can **mitigate such a bias** and **enhance mapping and variant calling accuracy** for both germline and somatic variants.

Personalized graph construction and analysis

Mapping statistics & reference bias

Somatic SNVs & indels analysis

Driver analysis: erasing the hg38 errors

Pangenome in cancer phylogeny
